

Question 1: What confused you and how did you resolve it?

One thing that confused me was getting the AI response to address leads by first name only — my system prompt referenced `{{ $json.Name }}`, but since the sheet stores full names, every response greeted leads with their full name instead. I resolved it by noting this as a fix for later: splitting the first name out before passing it to the prompt.

Question 2: What human review step would you add before sending?

If I were launching this as a real feature, I would add a human review step for any response that uses the fallback phrase, since those indicate the agent couldn't answer confidently — those are the highest-risk emails to send unreviewed. I'd also flag responses that mention specific numbers (pricing, response times) for a quick accuracy check before sending.

Question 3: How would this change at 500 leads per day?

At 500 leads per day, I would need to replace the manual trigger with a Schedule Trigger, add rate-limiting logic to stay under Gemini's free-tier request cap, and move off the In-Memory Vector Store to a persistent one, since in-memory storage clears on restart and can't reliably handle that volume.
